Statistical Analysis of Coding Sequences

Set-up of an R package statanacoseq distributed on GitHub to carry future implementations of Codon Bias Indexes. Master Thesis 2016
presented on August 12 2016
at the Faculty of Science
Institute of Plant Sciences (IPS)
in the master program of Bioinformatics
University of Bern and University of Fribourg

for the master degree in Bioinformatics and Computational Biology by

Fredy Siegrist

accepted on the faculty reunion:

Declaration

under Art. 28 Para. 2 RSL 05

Last, first name: Siegrist Fredy

Matriculation number: 99-119-380

Programme: Bioinformatics and Computational Biology

Thesis title: Statistical Analysis of Coding Sequences

Thesis supervisor: Dr. Cannarozzi Gina

I hereby declare that this submission is my own work and that, to the best of my knowledge and belief, it contains no material previously published or written by another person, except where due acknowledgement has been made in the text. In accordance with academic rules and ethical conduct, I have fully cited and referenced all material and results that are not original to this work. I am well aware of the fact that, on the basis of Article 36 Paragraph 1 Letter o of the University Law of 5 September 1996, the Senate is entitled to deny the title awarded on the basis of this work if proven otherwise. I grant insprection of my thesis.

Introduction

This document is written based on a Generic EPFL Thesis Template in LaTeX v. 5.57 and is SUBDUE to further changes as it should be included in the GitHub project and some of the Chapters should contain text elements that are used to build up a proper R vigniette of the package. Meaning to give examples for the usage of the different indices and functions for biological interpretation with the code for repeating the *in silico* experiments by applying the code lines step by step or by copy pasting the entire code for a sample experiment wich raw data can be found in a public database. . . .

0.1 Aim

We are aiming to set up a tool to automatically calculate and evaluate statistical properties of codon bias, especially implementing the calculation for different codon bias indices and for genes of organisms where its genome is sequenced for the most part. That means that we have at least a partially sequenced genome and the information on expressed sequences or protiens The most simpple calculation of codon bias is the GC content of the third base of synonymous codons of a single gene or coding DNA sequence (CDS). This codon bias reflects neutral mechanisms like mutational selection for a high or low GC content in an organism. . . . reference . . .

Such mechanisms based on a single gene can be revised by incorporating species independent information of general translation efficiency and RNA folding. Moreover, instead of analysing a single nucleotide position alone (mononucleotides), information on cytosine (C)-methylation can be taken into account and calculation on dinucleotides (GC) for mammals or quadnucleotide (GATC) or pentnucleotides (CCWGG) wich harbours a degenerate nucleotide position that can be A or T. The succession of codons (bicodons or even tricodons) may of course also be of interest but may only refine codon bias indexes where information on the whole genome or even for species is taken into account.

When we aim for introducing a little bit more suffisticated indexes, they will depend on

additional information such as, the transcriptome, the genome, gene expression, tRNA availability

One aspect for some codon bias mesurements is the definition of the optimal codon, thus the one with the most desirable quality. This information is used to mesure the frequency of optimal codons (Fop) or the P1 index, a meaure of the influence of tRNA availability. Which of the codons is optimal can be manifoldly defined, such as predicted using the tRNA gene copy number as a indicator as tRNA levels correlate with gene copy number in general [Chaney and Clark(2015)](Chaney and Clark 2015).

0.2 Teff genome

Eragostis tef is not only a grass but an important crop, that was neglected in socientific studies before the setup of the 'Teff Improvement Project" ten years ago at the University of Bern. Applied science generated improved plants that made it to the farmers in Ethiopia and research is ongoing to discover new break-through plants that show increased seed size, soil acidity, drought and herbizide tolerance along with the improved yield and to maintain lodging resistance without being semi-dwarf. A valuable resource for plants genetics is also the sequencing and annotation of the tetraploid genome of Teff and the evaluation of its properties [Cannarozzi et al.(2014)Cannarozzi, Plaza-Wüthrich, Esfeld, Larti, Wilso Therefore, we used as sample organism here, sequences from this genome to examine what obstacles one encounters by working with a almost totally sequenced but not yet fully annotated genome. By learning from its codon usage, variations generated by technologies already used in the 1960 for screening of genetic variations of agricultural plants combined with DNA sequencing technologie may improve the selection criterias for optimal mutants used for back crossing.

1 Setup of data and project

In this chapter we will see some examples of tables and figures.

1.1 Getting familiar with the data

Before the project was set-up the initial task was to gather information for calculating one of the first defined and most basic codon bias index called frequency of optimal codons (Fop). The optimality of a codon can be estimated by the usage in the given gene, the transcriptome or by accessing the numbers of tRNA genes found in the genome. As we have already the data of tRNA genes for the teff genome available, this was the choice to work with and to import the information for closely related species for mays and millet.

1.1.1 read tRNA stats and decide on optimality of a codon

```
#03.01.2016 Master project read in stat files from view-source:http://gtrnadb.ucsc
     .edu/GtRNAdb2/genomes/eukaryota/

```

However this code had to be adapted because it is only reading in the tRNA genes with introns.

1.2 text chunk - tRNA database

The tRNA genome numbers for eukariotic, bacterial, archaea and one viral genome was extracted from tRNAscan-SE v.1.3 run statistics of the GtRNAdb 2.0 (available at Genomic tRNA Database 2.0, http://gtrnadb.ucsc.edu/GtRNAdb2/genomes/).[Chan PP et al. 2016]

To decide on optimal codons the number of genes for the given anticodon was divided by the maximal number of genes for a anticodon for the same aminoacid to give fraction

Chapter 1. Setup of data and project

to optimal codon. The codon was accepted as optimal if this fraction was 1. In a list for every genome with available run statistic data, a frame with aminoacid, codon, number of genes, fraction to optimal codon, fraction to all codons, and the decision if it is a optimal codon was stored for the four superkingdoms seperately.

```
The genomes with names containing \# or * have to be treated as special cases, as even the browser failed to fetch the files. Therefore \# was replaced with \%23
```

However, in those run statistics, from vertebrates especially non-primate mammals, are littered with tRNA-derived repetitive elements with primary sequences very similar to real tRNAs. So they apply a non-unveiled post filter after the tRNAscan-SE on those genomes before depositing the predictions to GtRNAdb. Therefore, and because they were not willing to share the database with the summary statistics, these had to be rebuild from scanning the headers of the fasta files. Therefore the fasta file name had to be scanned in the index.html file and the fasta files were renamed according to the directory name to facilitate automation.

The statistics is now enhanced by an 65th line containing undefined aminoacid all other anticodons with degenerated base information are counted to the undefined species (as they do in the summary page)

codon ramp (rare codons at the start Tuller et al.) "This "codon ramp" hypothesis should apply primarily in the context of strong translation, but we found that using rare codons at the N terminus increases expression regardless of translation strength." –ANECTODE—When analysing the moving average of the optionality factor of the codons for the tRNA genes, we don't really detect a codon ramp at the 5' terminus, first, but the first codon was always optimal. No wonder because there is only one codon for Methionine, the start codon. Therefore we should only analyse the aminoacids that have a choice of anti-codons to use.

For analyzing codon usage in E. teff Gina's validated protein-transcript fasta files were used, however there were two issues in the database: first one of the proteins (Et_s4372-0.17-1) was truncated, didn't startet with methionine and was not corresponding to the truncated transcript, secondly the number of transcripts matched the number of proteins, but there was one orphan entry on each side (Et_s2692-0.26-1, Et_s14755-0.7-1), that had to be filled up with the corresponding entry of the other datafile.

1.2.1 Plot OCU demo

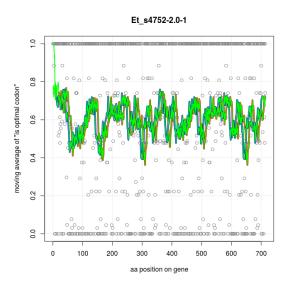

Figure 1.1: A sample figure (from plot OCU demo(plot(OCU)), of statanacoseq, got from https://github.com/fredysiegrist/statanacoseq).

2 R package setup and maintenance

In this chapter we will describe the generation of the R package structure, implementation in R Studio and hosting on GitHub.

2.1 Generation of R package

The first intention was to generate a package named "statanacoseq" in the linux version of R. The name is pretty long and has not been found to be used as R package name anywhere else, that is screened by google. Setting up of the R package has been done with the help of devtools, some few lines of code generate a backbone that then can be filled with the content and basically be packed after having put the first function in to an R file.

```
demo(plotOCU)
demo(Fop)
```

In this case a simple function with misleading name was countcodonfreq but was used to check the 'validated' fasta files by printing out the fraction of codons to aminoacids for the nucleotide and aminoacids with the same entry name.

```
countcodonfreq <- function(no=1, wdir="/windows/R/") {
    require(seqinr)
    list(myseq, myaa) <- mylist(wdir)
    print(length(myseq[[no]])/3/length(myaa[[attr(myseq[[no]], "name")]]))
}</pre>
```

2.1.1 Maintenance with R Studio

To be more efficient in managing the project the project initiated with devtools was imported into R Studio, a software package that brings many functions for assisting with R code writing, documentation and communication with the version control system [RStudio Team(2015)].

2.1.2 Publishing on GitHub - Description of versions

After the package got the first function to work independently on sample data from the package it was submitted to GitHub, a hosting service for software projects, for version control and to make it available for revision. The origin is placed at https://github.com/fredysiegrist/statana [Charles(2013)]. Since no version has been generated where the indices that are not implemented in Darwin has been drawed up, the version remained at 0.0.0.900x, marking it as under development. At the moment of writing this text the version is 0.0.0.9001 and will be set to 0.0.0.9002 for the evaluation of this work and 0.0.0.9003 after the corrections. Any further version will mark improvements to the code made post thesis submission.

The version 0.0.1 should mark the mile stone of achieving better performance than the Darwin package, incuding the calculation of not-implemented functions in that code.

Version 0.1.0 should be the version that is distributed to the scientific community and following versions may be described in articles.

Version 1.0.0 will be defined after distribution to CRAN or bioconductor, if a bug free code that is consistant in it-self is created and will have some back-references from other packages.

3 Transcription of Darwin Code

In this chapter we will describe the transcription of darwin codes and the adaptation of some function to the R enviorenment.

3.1 Transcription of Darwin functions

One of the tasks was to set up a system that can handle the functions implemented in Darwin in the source compilation *CodonIndices* and process genetic files given from local fasta files, sequence files from public databases or sample files from the R package if no custom sequence is entered. The remaining problem is to understand how the variable *Entries* is build up from the database *db* and to mirror that function as we built up the R package on the existing R project SeqInR *seqinr* that uses a distict different sequence database handling. Some other functions, where indices are calculated on the sequence information itself, where adaptable without dealing with the sequence database problem and were transcribed 1:1 to a function R code, however the loops are not acknoledging the functionality of the R environment.

3.2 R environement adaptation

To upvalue the code transcibed from Darwin, the function *ComputeNEC* was simplified to R language by eliminating the loops and introducing table and sapply function instead. The source code now looks pretty much like a R code that was setup in that language at first (by me). Below we list this code for demonstration, the original code in Darwin can be found in the appendix.

```
1 ComputeNEC <- function(cds) {
2    if(!(checkCDS(cds))) {stop("non valid CDS)", call.=FALSE)}</pre>
```

Chapter 3. Transcription of Darwin Code

```
3
     else {
        cds <- tolower(cds)</pre>
5
        cod <- rep(0, times=64)
       names(cod) <- sapply(as.character(Tef$codons), reversecomplement)</pre>
6
        cod < -cod[c(-59, -60, -64)]
       aa <- rep(0, times=20)
8
       names(aa) <- levels(Tef[,1])[c(-16,-18)]
9
       cods \leftarrow count(s2c(cds), word = 3, by=3)
11
        cod[names(cod)] <- as.vector(cods[tolower(names(cod))])</pre>
       AA <- table(translate(s2c(cds)))
12
        aa[names(aa)] <- AA[a(names(aa))]</pre>
13
        NC <- rep(1, times=length(aa))</pre>
14
       names(NC) <- names(aa)
15
       Acods <- sapply(names(NC), function(i) sapply(as.character(Tef[,2]),
16
         reversecomplement)[Tef[,1]==i])
17
        contributors <- names(aa)[sapply(Acods, length)>1&aa>1]
18
        Nc <- sapply(contributors, function(i) {</pre>
19
        n <- sum(cod[unlist(Acods[i])])</pre>
         S \leftarrow sum(sapply(cod[unlist(Acods[i])], function(x) (x/n)^2))
        F <- (n*S-1) / (n-1)
21
22
        return(1/F)
23
        }
24
        )
       NC[contributors] <- Nc[contributors]</pre>
25
26
       return(sum(NC))
27
28 }
```

4 Vignette

5 Outlook

In this chapter we will give a brief overview on what Indices are meant to be implemented in the future, what results could be generated by applying them and what the future for this package looks like.

5.1 Codon Bias Indices

There are dozens of codon bias indices that yet have to be implemented in the package. The original Darwin code has alredy defined some of the most wanted indices yet to be implemented. Here is an overview on the implemented, the ones which have a void function backbone and the non-implemented functions:

The table 5.1 is a floating table showing which indices have already been implemented in statanacoseq.

5.2 Biological meaning and statistics

The basic idea of a statistical analysis package for codon analysis is to combine the most frequently used codon indices in one software to evaluate which of them is best performing regarding to the availability (quality) and the biological properties for the given species. By putting it into the environement of the statistical open source program R following analysis steps as correlation to Gene Ontology (GO) tags can be done without having to deal with data handling to other software. The open structure of R codes also allows to use other implementation of algorithms already developed for R as we here used the functions RSCU from seqinr package for example. That allows other scientist to work with there own interpretation of new indices or better implementation

of algorithms to calculate them. Furthermore, it is designed to adapt collaborators or third party code in the package, because every function has its own file and comes with the description of the function. The basic biological problem to solve, as soon as all the major indices are implemented, is to find correlations of indices or clusters with other biological information such as gene expression (that is already part of the calculation of some indices), intracellular location, stress responses, enzymatic families, pathways, development stages and many more. One possible approach is to correlate the index properties to GO attributes and to find out wether there are indices that are significantly representing some of them, in order that a prediciton of the function or other properties of unknown proteins can be predicted.

6 R package on GitHub

Here you can see a citation: [Council(1985)].

The project is hosted on GitHub and freely available for the scientific community interested in it: https://github.com/fredysiegrist/statanacoseq

To install the R package on a R version > 3.3.0 the following lines of codes are sufficient to load the package:

```
1  # install 3rd party software for communicating with GitHub
2  install.packages("devtools")
3  library(devtools)
4  # install software package of master thesis
5  install_github("fredysiegrist/statanacoseq")
6  library(statanacoseq)
```

To run a short demo on some of the functionalities one can now enter the following lines to test the package installation.

```
demo(plotOCU)
demo(Fop)
```

An appendix - the Darwin code for codon indices

In this appendix we list the CodonIndices file of the Darwin software package that was used to transcribed most of the functions of statanacoseq package.

Data Analysis and Retrieval With Indexed Nucleotide/peptide sequences homepage

Fredy SIEGRIST

Schnbergweg 11 CH-3006 Bern +41 31 511 0512

Objective: Master in Bioinformatics and Computational Biology

EDUCATION

2016 (ongoing), Universities of Bern and Fribourg, Switzerland, Master in Bioinformatics, English.

2011, Apr 13, University of Basel, Switzerland, PhD Cell Biology, English.

2003, Oct 24, University of Bern, Switzerland, Master Biochemisty, German.

1999, Jun 17, Gymnasium Bern-Kirchenfeld, Switzerland, Matura type C, German.

ACTIVITIES

Editorial Acitivities and Teaching

Served as referee for: BMC Research Notes (BioMed Central), International Journal of Interferon, Cytokine and Mediator Research (Dove Press).

Modular course in Clinical Medicine for bachelor students (University of Basel) Tracking down genes modern genetics in clinical research

Administration

Administrative Board Member, Moosbad Immobilien AG, Emmenmatt, Switzerland

Publication Record

h index / Sum of the Times Cited (Web of science) 5 / 317

Computer Experience

Programming Langugaes (OO): R, PHP5, Python, Java. Programming Langugages (procedural, script): Unix-Bourne-Shell / bash, DOS-Batch, GW-BASIC. Operating Systems: Windows, Ubuntu, MAC-OS, MS-DOS. Software: MS Office / LibreOffice, Oracle VM Virtual Box CMS: OpenText, Joomla, Adobe Experience Manager, LSF / SGE Networks: Windows Server, Novell NetWare Databases: SQL / MySQL, MS Access

Work Experience

Publisher (CMS), Webeditor, IT-Support, Brewery Assistant.

EMPLOYMENT

Publisher, Federal Food Safety and Veterinary Office, Liebefeld, Switzerland 2016, Feb - Mai

Scientific Associate, Clinic of Nephrology, Bern University Hospital, Switzerland 2014, Feb - Jul

Post-doc, Laboratory of Virology, University Hospitals of Geneva, Switzerland 2011, Mar - 2013, Feb

PhD, Molecular Medicine and Toxicology, Roche, Basel, Switzerland 2006, Mar - 2010, Sep

Trainee, Functional Genomics, Novartis, Basel, Switzerland 2004, Apr - 2005, Mar

33

SCIENTIFIC AFFILIATIONS

2016 International Society for Computational Biology 2008 - 2014 International Society for Interferon and Cytokine Research Fredy Siegrist Page 2

PROJECT SUMMARIES

Short-term scientific associate, University Hospital of Bern Department of Nephrology, Hypertension and clinical Pharmacology; Prof B. Frey Department of medical Oncology; Dr M. Zweifel Genome-mutations in the androgen-receptor ligand-binding domain in mamma- and ovarian carcinomas

Mutations in the androgen-receptor ligand-binding domain is addressed by next-generation sequencing in mamma-, ovarian- and prostate-cancer samples. Driver mutations will be analysed in-vitro for sensitivity to dihydrotestosteron derivatives in reporter assays. *Department of Nephrology; Prof U. Huynh-Do* Genomic analyses of chronic hypoxia exposed fetal kidneys

Kidney from mice embryos hold in a hypoxia chamber were analysed by microarrays and significant genes are verified by qPCR, in-situ hybridization and immunohistochemistry to validate expression. Epigenetic DNA status (MetC and hMetC) of candidate genes will be assessed by MeDIP-qPCR.

Post-doctoral position, University Hospitals of Geneva Laboratory of Virology; Prof L. Kaiser and Dr C. Tapparel Small RNA sequencing of rhinovirus infections

Deep sequencing data from small RNA Illumina libraries were analysed in rhinovirus infected cell culture samples, small viral RNAs are detected and human miRNA quantified. HeLa cells were infected with different rhinovirus types. Viral RNA fragments and human miRNAs were analysed with northern blots, primer extension and rapid amplification of cDNA ends assays. Impact of RNA fragments on viral replication and translation was addressed with quantitative PCR, Luciferase and immuno-fluorescence.

PhD Thesis, F. Hoffmann-La Roche AG Molecular Medicine Laboratories; Prof U. Certa SOCS proteins in IFN silencing

Function of SOCS Proteins in IFN signalling was studied by gene expression analysis with semi quantitative RT- qPCR. Selected candidates were cloned in a mammalian expression vector and fusion proteins with SNAP-tag (Covalys) were cloned and analysed with fluorescence microscopy. Stable SOCS expressing cell lines were generated and characterized for their interferon response by gene and miRNA expression microarrays and statistical analysis with R/Bioconductor. Bimolecular fluorescence complementation with eYFP and STAT1/2 fusion proteins was insensitive to STAT activation by IFN, but localization of STAT fusion proteins as for untagged dimers. Cell-to-cell transfer of a proliferation control protein (IFITM3)

The transfer of IFITM3 proteins from a generator cell to a recipient cell was assessed by fluorescence microscopy, eYFP marked cell lines were sorted by FACS and analysed for protein transfer by immunoblotting. Protein transfer and proliferation assay (metabolite calorimetry, BrdU ELISA, FACS) excluded transfer of cytostatic effect. Phylogenetic analyses demonstrated recent IFITM gene development.

Traineeship, Novartis Pharma AG, NIBR, Basel Functional Genomics Group; Dr F. Natt siRNA stability in biological fluids

Obstacles for siRNA therapeutics are siRNA delivery and the short half-life of non-modified oligonucleotides. I have established a method for rapid analysis of degradation and demonstrated benefit of novel siRNA modifications (especially at their 3 overhang) for serum stability. I synthesized siRNA derivatives together with hydrolysis-stable MOE-RNA standard marker and analysed degradation of differently modified siRNA with HPLC, CE and Gel- electrophoresis. Furthermore, I have specified mechanism of degradation using LC-MS.

Diploma Thesis, University of Bern Department of Chemistry and Biochemistry; Prof R. Haener Construction and analysis of a cis-acting Ribonucleasemimic

Ribozyme mimics are generally linked to a nucleic-acid-backbone for specific recognition of the targeted gene transcripts. Efficient substitutes for the big catalytic domain are metal complexes like Cutrpy for example. I have demonstrated self-cleavage of a RNA-Cutrpy-based ribozyme mimic at a specific phosphordiester bond. Main work involved the RNA backbone design (single bulge cleaving site), RNA modification (functional and radioactive / fluorescence labelling) and purification. Finally, triggering of cleavage and analysis of RNA degradation (PAGE).
